

# Shake-the-Box

Lagrangian particle tracking at unprecedented tracer particle density **4D-PTV**, as a time-resolved volumetric flow measurement technique, has recently regained a whole new level of attention by the introduction of the award winning\* "**Shake-the-Box**" method [1]. Traditionally PTV has suffered from a poor spatial resolution due to its limitation of measuring flows with a low particle seeding density. Utilizing the temporal information in addition to iterative particle reconstruction [2], now "**Shake-the-Box**" allows Lagrangian particle tracking at **unprecedented tracer particle density and positional accuracy** [1]. It is applicable at seeding densities as high as - or even higher than - the most sophisticated volumetric flow measurement systems so far (e.g. Tomographic PIV).

## Advantages

Extracting individual Lagrangian particle tracks at high seeding densities is offering **unique advantages** compared to traditional measurements on a Eulerian measurement grid:

- the spatial resolution for average fields and Reynolds stresses is not limited to the PIV grid resolution anymore. Using a large number of snapshots, the **spatial resolution can be increased** to the pixel level or even below [3].
- time-resolved tracking allows more precise velocity and acceleration estimation (see Fig. 1 below).
- > precise knowledge of the material derivative enables reliable pressure estimation [4].

**Computation time is reduced dramatically,** moving from the time and space consuming voxel representation of Tomographic PIV to individual particle tracks. Typically, the computation time is **10 to 100 times less** than for Tomographic PIV.

*Figure 1:* Shake-the-Box results for a free jet in water\*\*. *Velocity* (left) and *acceleration* (right). Recorded, calculated and displayed in LaVision's *DaVis* software
